Enormous Potential Benefits in Globalization of Knowledge

Benefits

- **Health:** Sharing Data Sets for research and disease control
- **National Security:** threat prediction, law enforcement
- **Data Analytics:**
 - Traffic re-routing,
 - smart energy usage,
 - economic growth by intelligent consumer targeting
 - risk predictions for financial markets

Risks

- **Loss of Control:** Remote Storage & Computation threatens
 - Authenticity.
 - Correctness.
 - Availability.
- **Loss of Privacy:** reveal more data than necessary to extract the benefits
 - Loss of Anonymity
 - Loss of Fairness: profiling, price discrimination
 - Loss of competitive Edge: playing field leveled by common data

Methods Which Don't Work

- **Classic Encryption:** Can hide information but not process it
- **Classic Anonymizing:** Individual's data with identifying information removed, is still easy to recognize

Benefit vs. Risk

- **Medical:** Research progress vs. Patient Rights
- **National Security:** Surveillance vs. Liberty
- **Financial:** Risk Analysis vs. Market-Competition
- **Economic Growth** Consumer Targeting vs. Fair Pricing

Are These Contradictory Constraints?

Benefit vs. Risk

- **Medical:** Research progress vs. Patient Rights
- **National Security:** Surveillance vs. Liberty
- **Financial:** Risk Analysis vs. Market-Competition
- **Economic Growth** Consumer Targeting vs. Fair Pricing

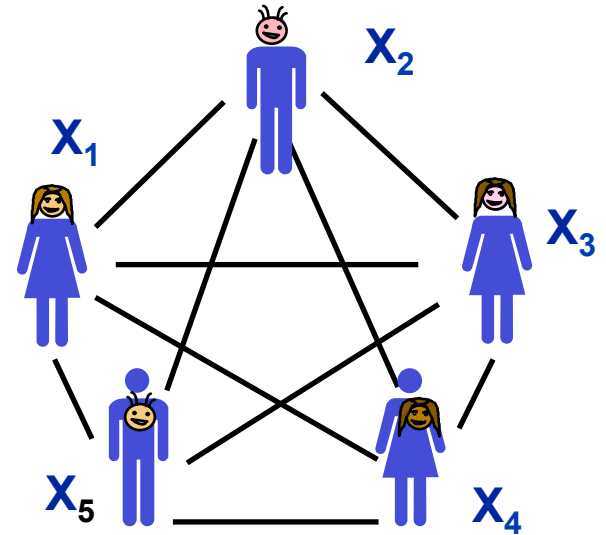

Can mathematics & technology enable us to have the best of both worlds

Cryptography 80's - today

- Host of Techniques that enable to perform computations on data without seeing the data
- Extract specific knowledge, revealing nothing extra
- Reconcile some of these seemingly contradictory "Benefits vs. Risks"

SFE: Mathematical Formulation

N distrustful parties run a **protocol** to extract information depending on their collective private data.

Formulate this as evaluating a function

$$f(X_1, X_2, \dots, X_n)$$

- where X_j is private input of party j .

So that parties **only learn** the function **output**, but **nothing else** about others inputs

Example 1: Conduct Medical Study on Confidential Medical Data

$f(\text{B\&W-DNA}, \text{MGH-DNA}, \text{Pharma}) = \text{develop drug if the green gene is prevalent in the population}$

$N=3$

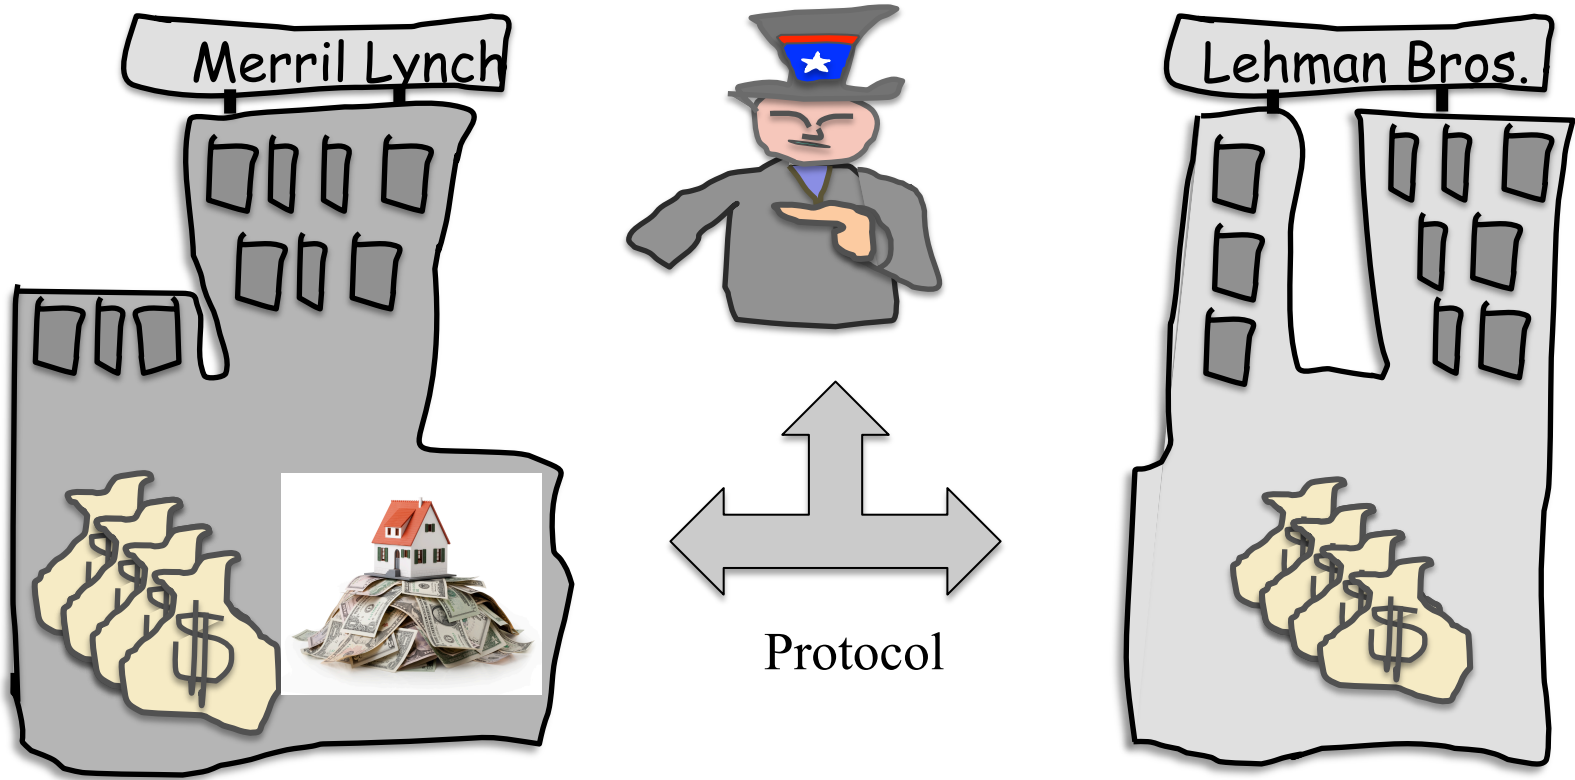

Example 2: Policing While Not Breaking Civil Liberties

$f(\text{photos}, \text{suspects}) = \text{true}$ only if suspect appears in them

$N=2$

Example 3: Financial Stability of our society [AKL11]

$f(\text{MerrillLynch info}, \text{LehmanBros info}, \text{Govt}) = \text{will banks become insolvent}$

$N=3$

Trusted Center Solution?

Goal: Decentralized solution with “same” properties as solution with trusted center

Major Result [the 80's]

Any polynomial time function f can be
securely evaluated,
using the *cryptographic tool box*

Unconditionally, if there is an honest Majority

Assuming oblivious transfer, if no honest majority,

Major Lesson: Store All Data Distributively

- In toy examples, different entities with different goals hold different parts of the data

Not Always the case....

- **By design can** store data so no single entity has entire data or power

SFE: Theory and Practice

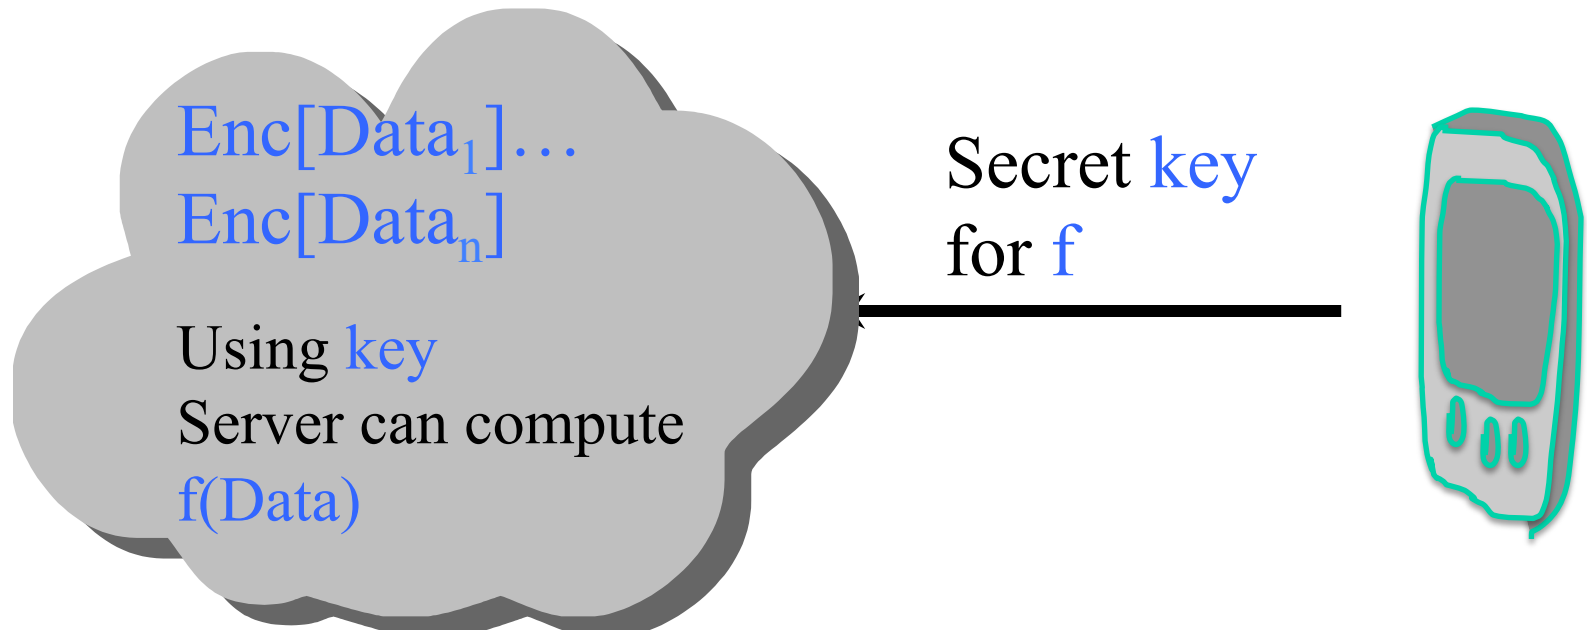

- [80's] Proof of Concept: Great Theory, for general functions, but impractical
- In recent times [Lindell2013 Survey]: optimized implementations for **simple classes but useful functions** and relaxed security, achieve impressive practical performance, much more work needed

But:

- Requires Interaction
- Not robust to an "insider" leaking all

Truly Amazing Progress: Computing on Encrypted Data

- Fully Homomorphic Encryption [Gentry2009]
- Functional Encryption [SW05, GVW13, GKPVZ13, GGHRSW13, GGSJ14]

- Theory to Practice: Research to be done

From Data to Programs

- Browsing
- Searching
- Social Interactions
- General Programs

Goal: keep *which* programs you run private?

Promise: Program Obfuscation Methods

Secure Function Evaluation \neq Privacy

- Given f , SFE shows how to compute $f(\text{data})$ revealing nothing extra on data

But

- $f(\text{data})$ itself may reveal too much
- $f_1(\text{data}), \dots, \dots, f_n(\text{data})$ may reveal too much
- $f(\text{data}_1, \dots, \text{data}_n)$ can reveal data_j , if $\{\text{data}_i\}$ is chosen maliciously

Differential Privacy Research: Which classes of functions are safe to compute?

A Combination of Privacy and Secure Computation

- A two-stage process:
 - Decide that the function/algorithm should be computed - an issue of **privacy**
 - Apply secure computation techniques to compute it securely - **security**

Security Definition: Simulation Paradigm

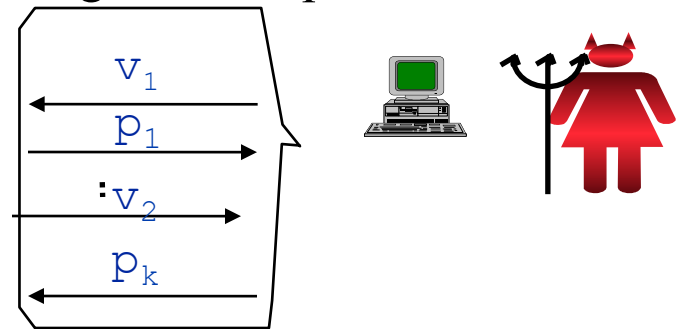

Given your own inputs and the output of the computation, can generate "simulated view" of the protocol which is **computationally indistinguishable** from "real view".

Distribution of
REAL Messages
Exchanged in the protocol

\approx

Messages
Exchanged in the protocol

Loss of Privacy is Complex

- Different Entities Collect and Protect Data in an Un-coordinated fashion
- Unforeseen Cross Referencing of information held by different entities on the same individual, causes greater privacy loss
- Aggregate information on many can reveals information on a single individual
