COMMENTARY

# Advancing Enhanced Oil Recovery as a Sequestration Asset

Sally M. Benson<sup>1,\*</sup> and John Deutch<sup>2</sup>

Sally M. Benson is a professor of energy resources engineering in the School of Earth, Energy & Environmental Sciences, co-director of the Precourt Institute for Energy, and Director of the Global Climate and Energy Project at Stanford University. Formerly, Benson was at Lawrence Berkeley National Laboratory, where she held a variety of key positions, including Deputy Director, Associate Director for Energy Sciences, and Director of the Earth Sciences Division. Benson is regarded as an authority on carbon capture and storage. She also uses energy systems analysis to help quide decisions about the most promising pathways for clean energy development.

John Deutch is an emeritus Institute Professor at the Massachusetts Institute of Technology where he has been a member of the faculty since 1970. He has served as Chairman of the Department of Chemistry, Dean of Science, and Provost. In the Carter Administration, he served as Director of Energy Research (1977-1979), Acting Assistant Secretary for Energy Technology (1979), and Undersecretary (1979-1980) in the US Department of Energy. He has been a member of the President's Nuclear Safety Oversight Committee (1980-1981), the White House Science Council (1985-1989), the President's Committee of Advisors on Science and Technology (1997-2001), and the Secretary of the Energy Advisory Board (2008-2016). John Deutch has published widely on technical and policy aspects of energy and the environment and has been a member of the board of directors or of the technical advisory committees of several energy companies.

#### Introduction

Avoided atmospheric  $CO_2$  emissions could be increased by accelerating the use of advanced  $CO_2$  enhanced oil recovery (EOR). Today, about 65 million metric tons of  $CO_2$  are pumped underground for enhanced oil recovery, mostly in the US. About one third of this  $CO_2$  is captured from anthropogenic sources. By doubling the amount of  $CO_2$  pumped underground for every barrel of oil produced, avoided emissions could be increased dramatically.

We propose that the US government pilot-tests a reverse Dutch auction for  $CO_2$  EOR credits to stimulate the development of advanced  $CO_2$  EOR. At an estimated cost of about \$25 per metric ton of  $CO_2$ , this compares favorably with other government programs designed to reduce  $CO_2$  emissions. Effective incentives would spur investments leading to gigaton-scale reductions that offset  $CO_2$  emissions from the transportation sector.

Carbon dioxide, CO<sub>2</sub>, injection is an enhanced oil recovery (EOR) technique especially effective at increasing production from deep light oil reservoirs. Studies suggest a global technical potential to sequester from 60 to 360 GT of CO<sub>2</sub> over the next 50 years, depending on the amount of CO<sub>2</sub> injected underground per barrel of oil produced.<sup>1</sup> For context, a path to a 2°C average global temperature increase is expected to require a total of about 125 GT of CO<sub>2</sub> storage.<sup>2</sup>

Achieving gigaton scale CO<sub>2</sub> EOR storage goals will require innovation. This work focuses on a government incentive—a reverse Dutch auction—as a sensible policy mechanism to encourage innovation of advanced CO<sub>2</sub> EOR (A-CO<sub>2</sub> EOR), whose commercial profitability derives from both enhanced production and CO<sub>2</sub> storage.

The United States and other countries are struggling to find fair and cost-effective ways to reduce carbon emissions to avoid the risks of climate change. When the oil and gas industry is facing mounting criticism as a business based on conversion of hydrocarbons in the ground to carbon dioxide emissions in the atmosphere, CO<sub>2</sub> EOR could be a concrete and positive contribution to CO<sub>2</sub> emission avoidance and deserves evaluation.

**Joule** 

Table 1. Properties and Assumptions Used in Hypothetical Analysis

Initial OIP: 180 Million Barrels	Primary and Secondary Production	Conventional CO <sub>2</sub> EOR at 2.5 bbl/ T <sup>a</sup> CO <sub>2</sub>	A-EOR at 1.25 bbl/ T CO <sub>2</sub>
Total recovery (% OIP)	33.3	50	60
Total oil recovery (million barrels)	60	90	108
CO <sub>2</sub> EOR oil recovery (million barrels)	0	30	48
CO <sub>2</sub> injected (MT) <sup>a</sup>	0	12.0	38.4
CO <sub>2</sub> emitted on use (MT) <sup>b</sup>	25.8	38.7	46.4
Net CO <sub>2</sub> emitted (MT) <sup>b</sup>	25.8	26.7	8.0
${\rm CO_2}$ emitted from incremental production (MT) $^{\rm b}$	-	12.9	20.7
Net CO <sub>2</sub> emitted from incremental production (MT)	-	0.9	-17.8

<sup>&</sup>lt;sup>a</sup>MT, million metric tons; T, metric ton.

At present, CO<sub>2</sub>-assisted EOR is about 3% of US domestic oil production or about 300,000 barrels (bbl)/day, mostly from the Permian Basin and the Gulf Coast.3 Historically, since most of the CO2 for EOR has come from natural CO<sub>2</sub> reservoirs, there has been little climate benefit. However, if CO2 EOR using CO2 captured from anthropogenic sources were increased about 10-fold to a level of 500 MT/year, that would reduce total US emissions by about 9.5%, not an inconsequential part of the emissions reductions that the United States is seeking to achieve by mid-century.

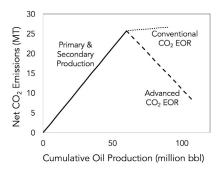

Figure 1. Net CO<sub>2</sub> Emissions over the Lifetime of an Oilfield as a Function of the Amount of Oil Produced

Net emissions are defined as the difference between emissions from burning produced oil (0.43 tonnes/bbl) and the CO<sub>2</sub> sequestered in the oil field during CO<sub>2</sub> EOR and A-CO<sub>2</sub> EOR (Table 2).

## Operation and Economics of CO<sub>2</sub> EOR

Primary and secondary production typically recovers up to one-third of the oil-in-place (OIP) in a reservoir. A-CO $_2$  EOR has the technical potential for doubling the recovery of OIP compared with conventional EOR. Normally a CO $_2$  EOR project will extend for decades with nearly all of the injected CO $_2$  remaining sequestered in the oil reservoir when produced CO $_2$  is recycled back into the reservoir.  $^4$ 

EOR projects are notorious for the high variability that reflects reservoir location and conditions. Project economics vary depending on the price of oil and the cost of CO<sub>2</sub> over the life of the project. Here, we use generalized results of prior studies of co-optimized CO<sub>2</sub> EOR plus sequestration. <sup>5–12</sup> For illustration, we focus on the hypothetical oil field described in Table 1 with 180 million barrels OIP. After primary and secondary production, we consider two cases: conventional CO<sub>2</sub> EOR and A-CO<sub>2</sub> EOR.

For this example, A-CO $_2$  EOR sequesters twice the amount of CO $_2$  per barrel of oil produced compared with conventional CO $_2$  EOR. Net emissions, defined as the emissions from burning the oil minus the amount of CO $_2$  sequestered from the oilfield are illustrated in Fig-

ure 1. During primary and secondary production, emissions increase linearly at a rate of 0.43 tonnes  $CO_2$ /bbl of oil produced. Once conventional  $CO_2$  EOR begins, sequestered  $CO_2$  nearly offsets the incremental emissions produced when the oil is burned. For A- $CO_2$  EOR, sequestered  $CO_2$  exceeds the incremental emissions from burning the oil, offsetting not only current but past emissions, eventually for this example, by 70% of all the emissions from primary and secondary production (Table 1, see Figure 1).

The economics of a  $\rm CO_2$  EOR project is sensitive to oil price, the acquisition cost of  $\rm CO_2$ , and additional cost associated with the EOR activity. Table 2 shows the range assumed in this work for "high," "reference," and "low" oil prices averaged over the project life. Table 2 includes the  $\rm CO_2$  acquisition cost and other costs associated with  $\rm CO_2$  EOR activity. <sup>13</sup> The values in Table 2 are subject to challenge but the trends of  $\rm CO_2$  price and margin with increasing oil prices are robust.

The margins are highly sensitive to oil price. Without an imposed charge on  $CO_2$  emissions, Table 2 shows that the projected cost of an A- $CO_2$  EOR is not financially attractive to the owner/operator compared with conventional  $CO_2$  EOR. The incremental costs to break even with traditional  $CO_2$  EOR range from \$22 to \$32/T  $CO_2$ .

#### **Policy Options**

The preferred approach of an economy-wide greenhouse gas emissions charge is unlikely in the near term. If, in the future, a charge is adopted at sufficiently high levels, the value of using the pores in oil reservoirs for sequestration will be greater than the value of the oil displaced, and the economic motivation for  $CO_2$  EOR production and sequestration will reverse.

In the absence of a carbon emission charge, there is no commercial

 $<sup>^{</sup>b}$ 0.43 metric tons emitted CO<sub>2</sub> per barrel of oil.

Table 2. Economic Analysis of CO<sub>2</sub> EOR and A-CO<sub>2</sub> EOR

Oil Price (\$/bbl) <sup>a</sup>	Conventional CO <sub>2</sub> EOR (2.5 bbl/T)			A-CO <sub>2</sub> EOR (1.25 bbl/T)		
	100	75	50	100	75	50
CO <sub>2</sub> acquisition cost (\$/T)	-39	-29	-19	-39	-29	-19
CO <sub>2</sub> acquisition cost (\$/bbl production) <sup>b</sup>	-15	-12	-8	-31	-23	-15
Other related costs (\$/bbl) <sup>c</sup>	-35	-35	-35	-56	-56	-56
Net pretax margin (\$/bbl)	50	28	7	13	-4	-21
CO <sub>2</sub> EOR production (million barrels)	30	30	30	48	48	48
Project EOR margin (\$ million)	1,488	854	219	634	-197	-1,027
CO <sub>2</sub> injected (MT)	12	12	12	38.4	38.4	38.4
CO <sub>2</sub> price to break even (\$/MT)					27.35	32.45
Project margin (\$/million) if credited with the social cost of carbon (\$30/T) for incremental storage					955	125

<sup>&</sup>lt;sup>a</sup>This range is narrower than the EIA 2017 AEO's \$30 to \$194 per barrel in 2030.

justification for private industry to invest in A-CO<sub>2</sub> EOR technologies. In this circumstance, the government objective should be to adopt policies at reasonable cost that will encourage EOR owner/operators to explore A-CO<sub>2</sub> EOR to position the industry to deploy this technology more rapidly when there is an economy-wide price on carbon emissions. The government has the choice of several policy mechanisms for this purpose:

• A tax credit for EOR. Since 2008, qualifying CO<sub>2</sub> EOR facilities have been eligible to receive a tax credit of \$10/T, with a cap of a total of 75 MT, referred to as the 45Q tax credit. In 2018, Congress raised the 45Q credit to \$35/T for CO<sub>2</sub> EOR and \$50/T for storage in saline formations and removed the cap. <sup>14</sup>

The 45Q tax credit will incentivize conventional  $CO_2$  EOR. But this tax credit mechanism is not targeted to incentivize A- $CO_2$  EOR. Furthermore, the use of tax credits suffers from "leakage" to financial intermediaries, and in the circumstances where oil prices are low, few oil and

gas firms are in a position to take advantage directly of the incentive. Recent cuts to corporate tax rates also make tax credits less attractive than in the past.

- A direct payment also does not incentivize development of A-CO<sub>2</sub> EOR beyond what would be expected under market conditions. To be effective, the level of payment would need to be sufficiently high to offset the current cost of CO<sub>2</sub>. However, the great diversity and uncertainty in the discounted net present value to owner/operators of multiyear EOR projects makes this approach more expensive than a targeted benefit.
- What is needed is a policy mechanism that allows the government the flexibility to adjust the amount of assistance provided to the firms prepared to undertake new projects at various levels of support. A reverse Dutch auction is an ideal mechanism to achieve selective encouragement of A-CO<sub>2</sub> EOR. In a reverse Dutch auction, the government would annually solicit bids from owner/operators of new A-CO<sub>2</sub> EOR multiyear projects

that, over the life of the project, specify the amount of CO<sub>2</sub> sequestered, the ratio of CO<sub>2</sub> sequestered to oil production, and the amount of annual payment sought from the government (which is assumed to be constant over the life of the project). These bids will reflect each firm's willingness to implement A-CO<sub>2</sub> EOR. In contrast to conventional tax credit or direct payment subsidy programs that offer the same benefit to all eligible firms, in a Dutch auction the government selects the price that yields the desired cumulative amount of A-CO<sub>2</sub> EOR.

It is difficult to predict the outcome of such reverse Dutch auctions for CO<sub>2</sub> EOR credits. The sizes and prices bid will depend on the oil price. It is quite possible that a \$20 per metric ton CO<sub>2</sub> payment would be sufficiently attractive to result in greater CO<sub>2</sub> EOR use in 2040 than the 700 million bbl/day predicted by the Energy Information Administration (EIA) in its 2014 Annual Energy Outlook (AEO). Rebound effects need to be evaluated that could increase oil consumption by the shift of the supply curve to a lower market clearing price.

The design of all these incentives for  $CO_2$  EOR confronts several complications:

• Should a benefit be extended to both low-cost natural sources and high-cost anthropogenic sources of CO<sub>2</sub>? Low-cost natural or anthropogenic sources (highpurity sources of CO2 from refineries and ethanol plants can be compressed and dehydrated for about \$20-30 T/CO<sub>2</sub>) of CO<sub>2</sub> can jump start the process, but in the future, anthropogenic CO2 will increasingly come from coal, oil, and natural gas combustion, which incur higher CO<sub>2</sub> capture, purification, and pressurization costs (ranging from \$60 to \$90/T CO<sub>2</sub> depending on the source).<sup>15</sup>

 $<sup>^{\</sup>rm b}$ A rule of thumb is that the acquisition CO<sub>2</sub> cost in \$/MCF (1,000 cubic feet) is between 2% and 4% of the oil price in \$/barrel. Cook, B.R. (2012) The Economic Contribution of CO<sub>2</sub> Enhanced Oil Recovery in Wyoming's Economy. The Enhanced Oil Recovery Institute, University of Wyoming. Working paper. p. 20.  $^{\rm c}$ Includes royalties, allocated EOR equipment allocation, taxes, recycling cost, and other site operation and maintenance costs associated with CO<sub>2</sub>.

## **Joule**

- The availability of a CO<sub>2</sub> gas pipeline distribution system is likely to be the greatest constraint to the expansion (at reasonable cost) of A-CO<sub>2</sub> EOR. A pipeline capacity constraint will lead to an increase in pipeline tariffs, a reduction in expected margins for A-CO<sub>2</sub> EOR, and hence attenuation in desired growth.
- An A-CO<sub>2</sub> EOR project will have a life of 10 years or more. The project entrepreneur must estimate the variability in oil prices and CO<sub>2</sub> acquisition cost in assessing the discounted present value of the project. Under current market conditions, there is a strong positive correlation between oil price, CO<sub>2</sub> cost, and return on CO<sub>2</sub> EOR projects.

How successful government policy will be at encouraging A-CO<sub>2</sub> EOR use and technology advance is uncertain for the reasons mentioned above. This uncertainty suggests that payments for A-CO<sub>2</sub> EOR using anthropogenic CO<sub>2</sub> with the Dutch auction proposal for CO<sub>2</sub> EOR be considered an experiment rather than a policy to be permanently adopted. A decade of experience will determine the merit of this policy incentive to encourage A-CO<sub>2</sub> EOR.

Experience gained from the expansion of A-CO<sub>2</sub> EOR will also be beneficial for assessing the costs and risks of CO<sub>2</sub> sequestration in deep saline formations, which have the potential for even larger amount of sequestration, but lack the financial and energy security benefits of CO<sub>2</sub> EOR. Let us assume a 3-year experimental program with ten

projects selected per year, each with a 10-year lifetime, and 300,000 bbl/per day produced for the entire program. If the government accepted an average bid for  $CO_2$  of \$25/T, the annual per project cost would be \$22 million for 0.88 MT of CO<sub>2</sub> sequestered. The total program cost over the lifetime of the program would be \$6.6 billion for 264 MT of CO<sub>2</sub> sequestered. The expense of the proposed CO<sub>2</sub> EOR program should be compared with other government programs designed to reduce CO<sub>2</sub> emissions. While largely presented in the US context here, the reverse Dutch auction could equally well be applied in other oil-rich countries seeking economically efficient policies for reducing emissions.
