

The Yowie Factor

**a simple estimate of
load rate during
climber fall arrest**

Dave Custer

Center for Sports Innovation

Massachusetts Institute of Technology

an overview of this talk

motivation

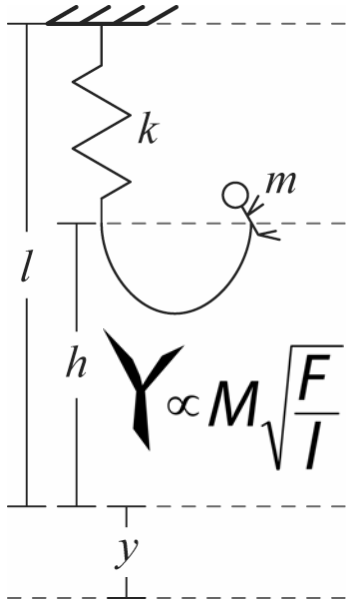

both ice and ice screws exhibit reduced strength with increased load rate. a 100 X increase in rate halves the strength.

objectives

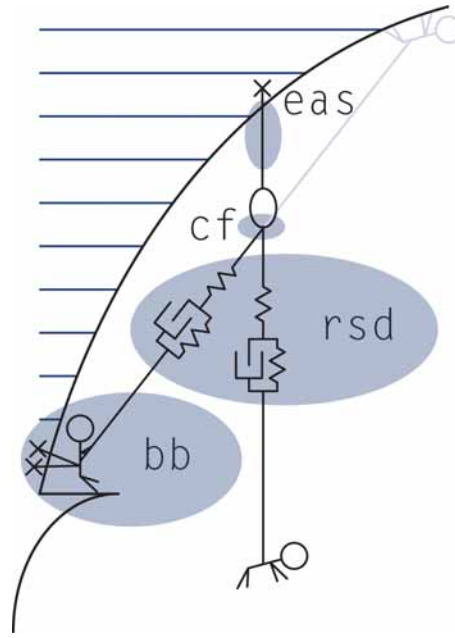

- determine degree of “impact”
- make impact accessible
- guide safety system design

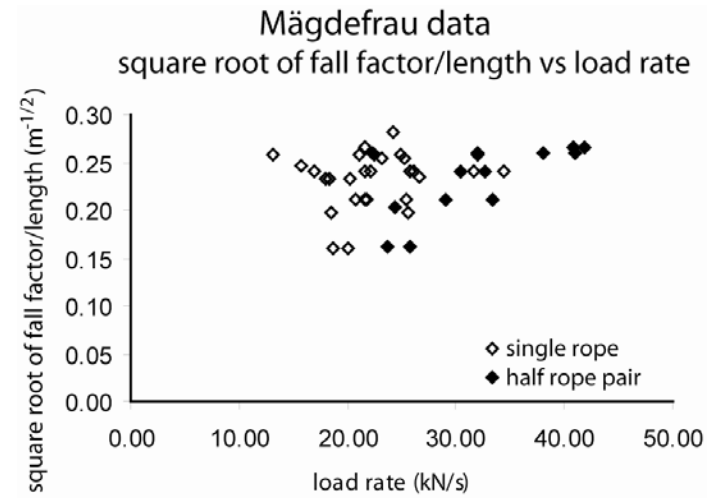

methods

determine the load rate based on a (very) simple rope model

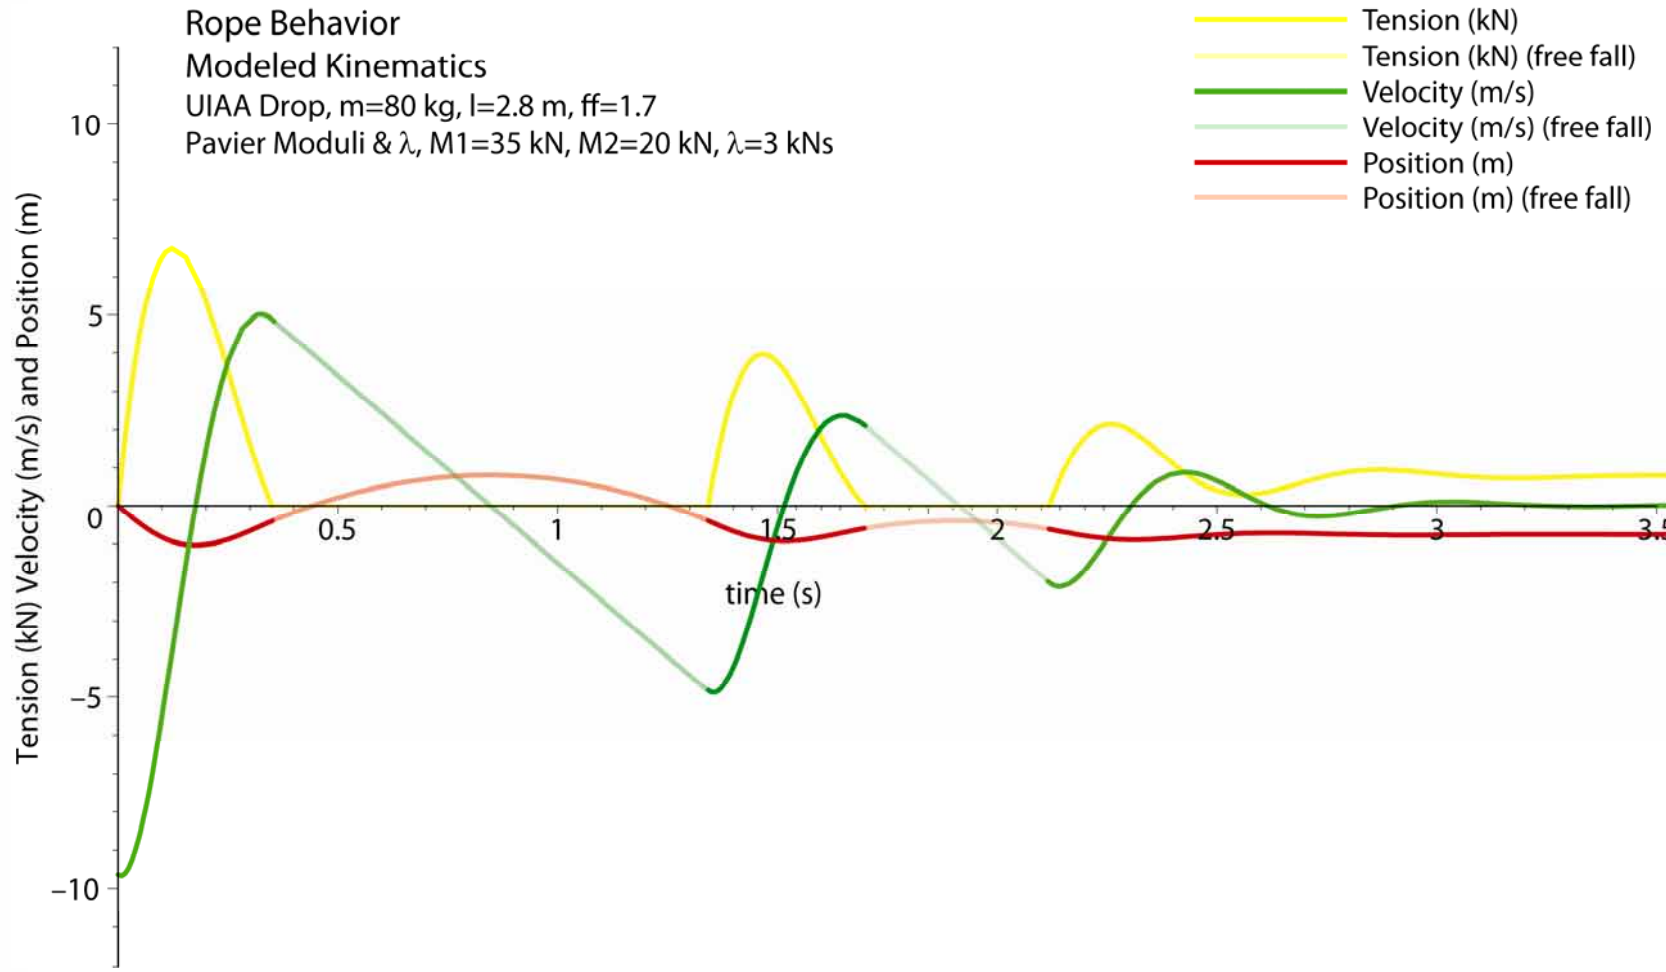

compare the simple model to complicated models (Wexler and Pavier)

compare the simple model to data (Mägdefrau)

expected kinematics behavior

the simple model

the potential energy of fall height is exchanged for energy stored in the stretched rope spring:

$$mgh = \frac{1}{2} m \dot{y}_{\max}^2 = \frac{1}{2} k y_{\max}^2$$

simple mass/spring oscillation:

$$f = -ky = m\ddot{y}$$

f : force on climber

\dot{f} : load rate

F : fall factor (h/l)

g : gravity acceleration

γ : tension ratio

h : fall height

k : rope's spring constant

l : rope length

λ : damping coefficient

m : climber's mass

M : rope modulus

\dot{y} : rope stretch

\dot{y} : climber velocity

\ddot{y} : climber acceleration

y : climber jerk

ω : oscillation frequency

Υ : yowie factor

(based on Wexler work)

the simple estimate of load rate

kinematics solutions:

$$\omega = \sqrt{\frac{k}{m}}$$

$$y = -\sqrt{\frac{2mgl^2 F}{M}} \sin(\omega t)$$

$$\dot{y} = -\sqrt{2gFl} \cos(\omega t)$$

$$\ddot{y} = \sqrt{\frac{2gFM}{m}} \sin(\omega t)$$

$$\ddot{f} = \frac{M}{m} \sqrt{\frac{2gF}{l}} \cos(\omega t)$$

$$\dot{f} = \frac{df(t)}{dt} = M \sqrt{\frac{2gF}{l}} \cos(\omega t)$$

$$Y \propto M \sqrt{\frac{F}{l}}$$

inclusion of potential energy of stretch

kinematics solutions:

$$\omega = \sqrt{\frac{k}{m}}$$

$$y = -\sqrt{\frac{2mgl^2 F}{M}} \sin(\omega t)$$

$$\dot{y} = -\sqrt{2gFl} \cos(\omega t)$$

$$\ddot{y} = \sqrt{\frac{2gFM}{m}} \sin(\omega t)$$

$$\ddot{y} = \frac{M}{m} \sqrt{\frac{2gF}{l}} \cos(\omega t)$$

$$\dot{f} = \frac{df_{(t)}}{dt} = M \sqrt{\frac{2gF}{l}} \cos(\omega t)$$

$$Y \propto M \sqrt{\frac{F}{l}}$$

a slight adjustment of boundary conditions leads to a 15%-20% increase in force, but no change in frequency:

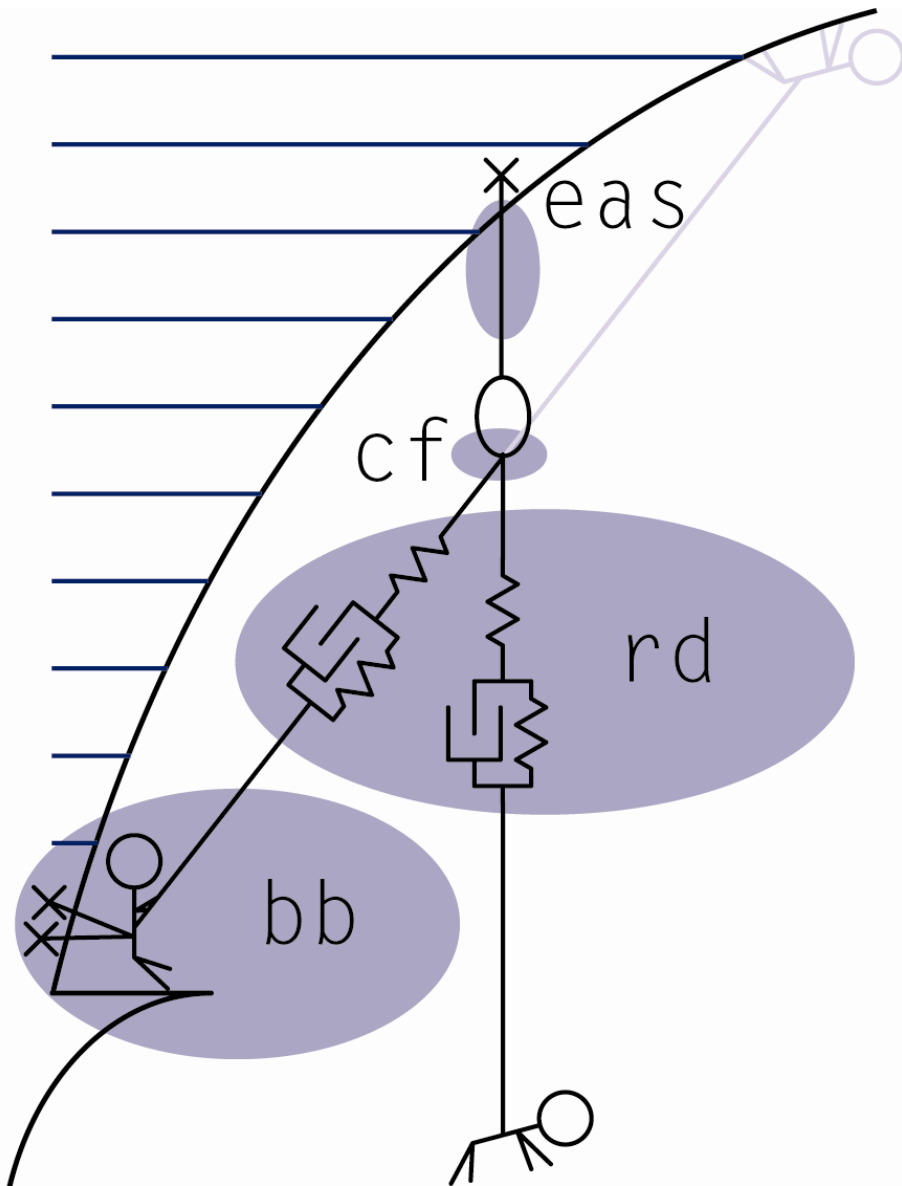

$$mgh + mgy_{\max} = \frac{1}{2}ky_{\max}^2$$

$$\ddot{y} = g \left(1 + \sqrt{1 + \frac{2MF}{mg}} \right)$$

$$\dot{f} = mg \sqrt{\frac{M}{lm}} \left(1 + \sqrt{1 + \frac{2MF}{mg}} \right) \cos(\omega t)$$

complications

- rope damping
- carabiner friction
- belayer behavior
- energy absorbing systems

how does one compare a spring to a damped spring system?

Wexler
spring
model

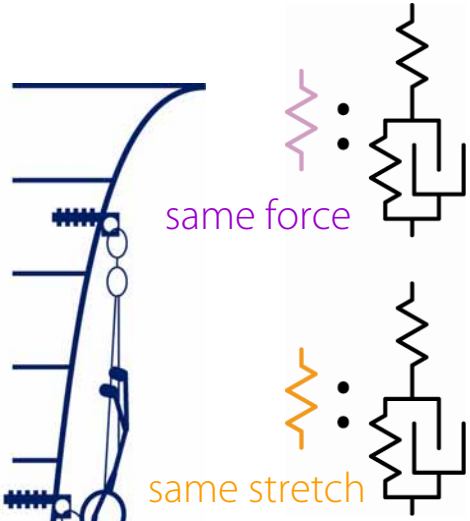

Pavier
spring
spring/
dashpot
model

I have
no simple
answer;
rather, 4
complicated
ones.

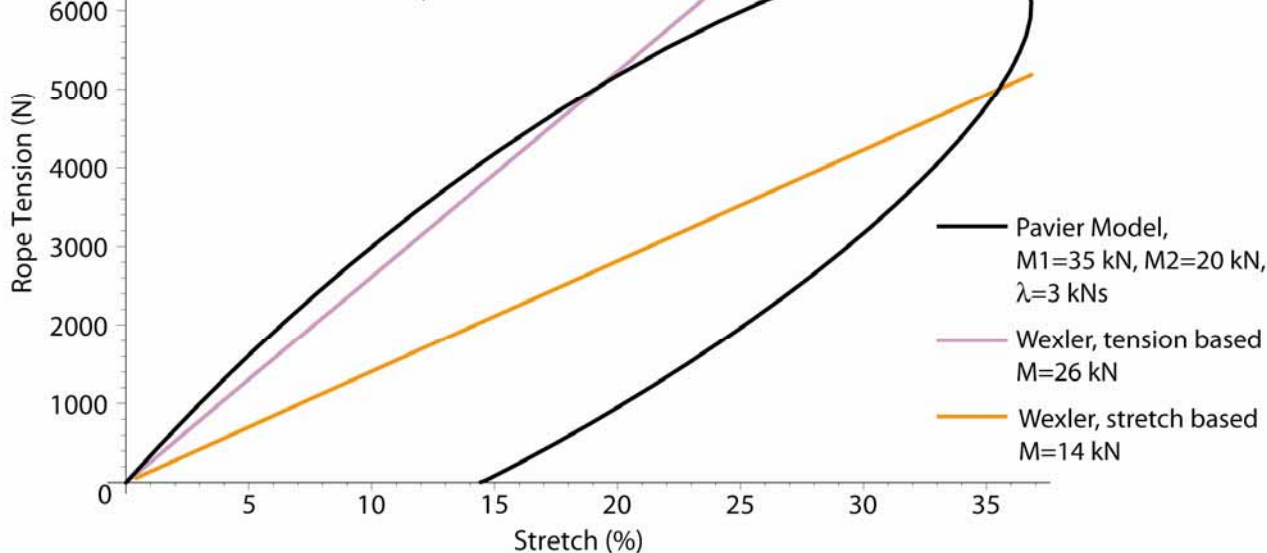

damping I

Rope Tension vs. Time
Comparison of Pavier Spring-Spring-Dashpot Model
to Wexler Simple Spring Models
UIAA Drop, $m=80$ kg, $l=2.8$ m, $ff=1.7$

Tension vs. Stretch Behavior
Pavier & Wexler Models
UIAA Drop

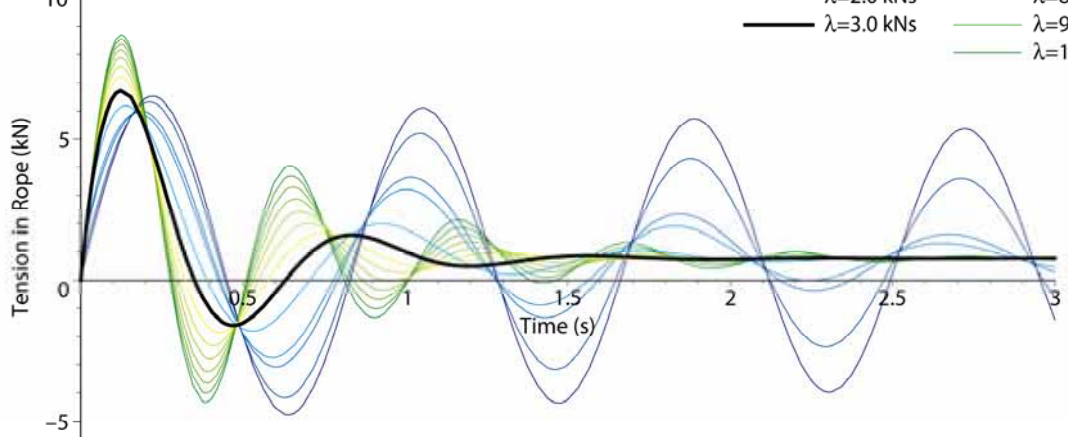

here, the
addition
of damping
increases
load rate

damping II

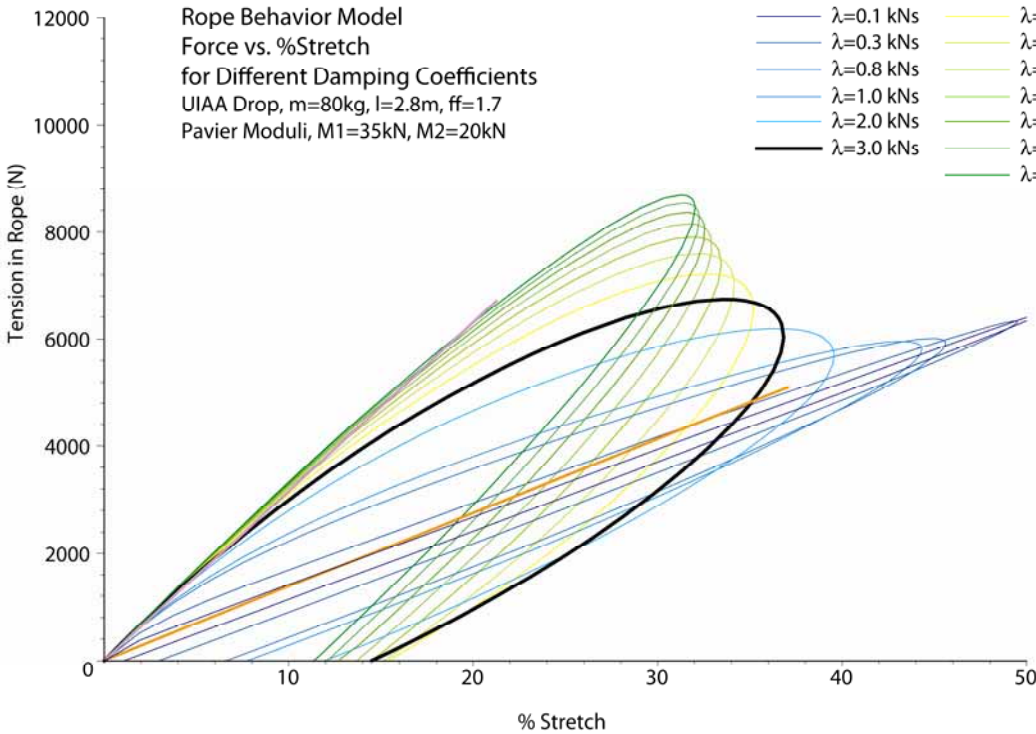

Tension vs. Time for Different Damping Values
Modeled for UIAA Drop Test and Pavier Moduli
 $M1=35\text{ kN}$, $M2=20\text{ kN}$, $m=80\text{ kg}$, $l=2.8\text{ m}$, $ff=1.7$

- $\lambda=0.1\text{ kNs}$
- $\lambda=0.3\text{ kNs}$
- $\lambda=0.8\text{ kNs}$
- $\lambda=1.0\text{ kNs}$
- $\lambda=2.0\text{ kNs}$
- $\lambda=3.0\text{ kNs}$
- $\lambda=4.0\text{ kNs}$
- $\lambda=5.0\text{ kNs}$
- $\lambda=6.0\text{ kNs}$
- $\lambda=7.0\text{ kNs}$
- $\lambda=8.0\text{ kNs}$
- $\lambda=9.0\text{ kNs}$
- $\lambda=10\text{ kNs}$

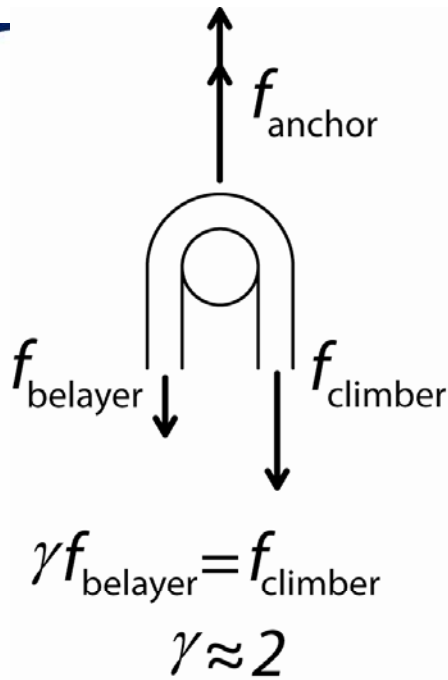

Rope Behavior Model
Force vs. %Stretch
for Different Damping Coefficients
UIAA Drop, $m=80\text{ kg}$, $l=2.8\text{ m}$, $ff=1.7$
Pavier Moduli, $M1=35\text{ kN}$, $M2=20\text{ kN}$

- $\lambda=0.1\text{ kNs}$
- $\lambda=0.3\text{ kNs}$
- $\lambda=0.8\text{ kNs}$
- $\lambda=1.0\text{ kNs}$
- $\lambda=2.0\text{ kNs}$
- $\lambda=3.0\text{ kNs}$
- $\lambda=4.0\text{ kNs}$
- $\lambda=5.0\text{ kNs}$
- $\lambda=6.0\text{ kNs}$
- $\lambda=7.0\text{ kNs}$
- $\lambda=8.0\text{ kNs}$
- $\lambda=9.0\text{ kNs}$
- $\lambda=10\text{ kNs}$

“critical” damping produces a load rate midway between the top spring and the two springs in series.

carabiner friction

1) increases the force on the top anchor but does not change the proportionality of the yowie factor

2) decreases the effective rope length and thus also

increases the fall factor; expect a 20% increase in load rate & reduced proportionality

$$l_{\text{effective}} = l \left(\frac{\left(1 - \frac{1}{\gamma}\right)}{2} F + \frac{1}{\gamma} \right)$$

belayer behavior

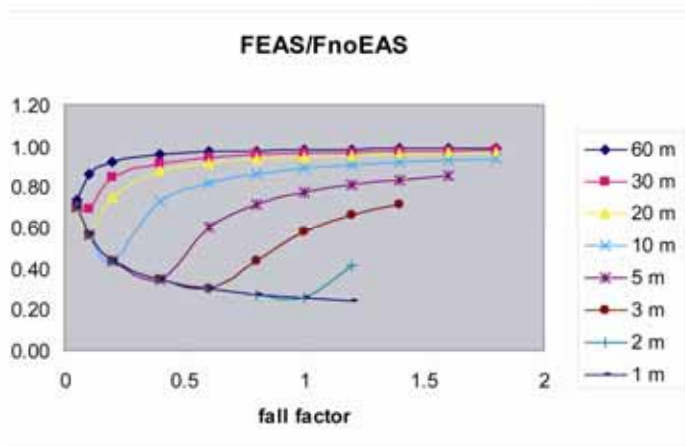

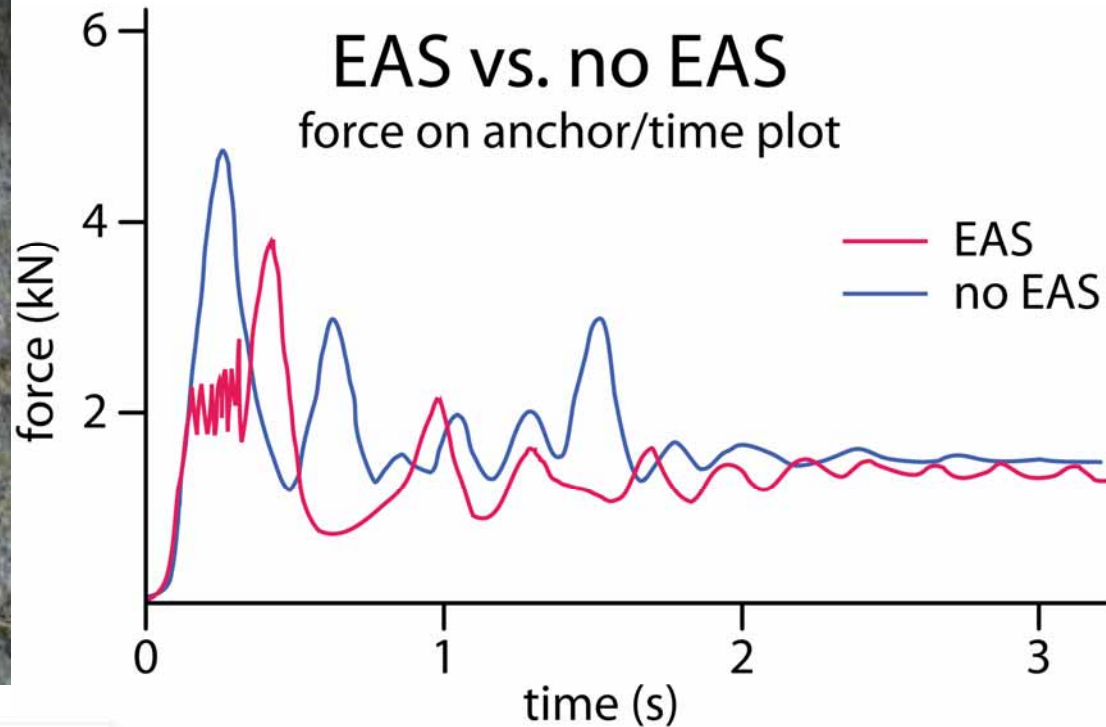

the belayer can reduce the energy absorbed by the rope by allowing rope to slip through the belay device and by being lifted up. the reduced energy results in reduced force, increased time, and thus reduced load rate.

$$mgh + mgy_{\max} = \frac{1}{2}ky_{\max}^2$$

$$\ddot{y} = g \left(1 + \sqrt{1 + \frac{2MF}{mg}} \right)$$

$$\dot{f} = mg \sqrt{\frac{M}{lm}} \left(1 + \sqrt{1 + \frac{2MF}{mg}} \right) \cos(\omega t)$$

energy absorbing systems

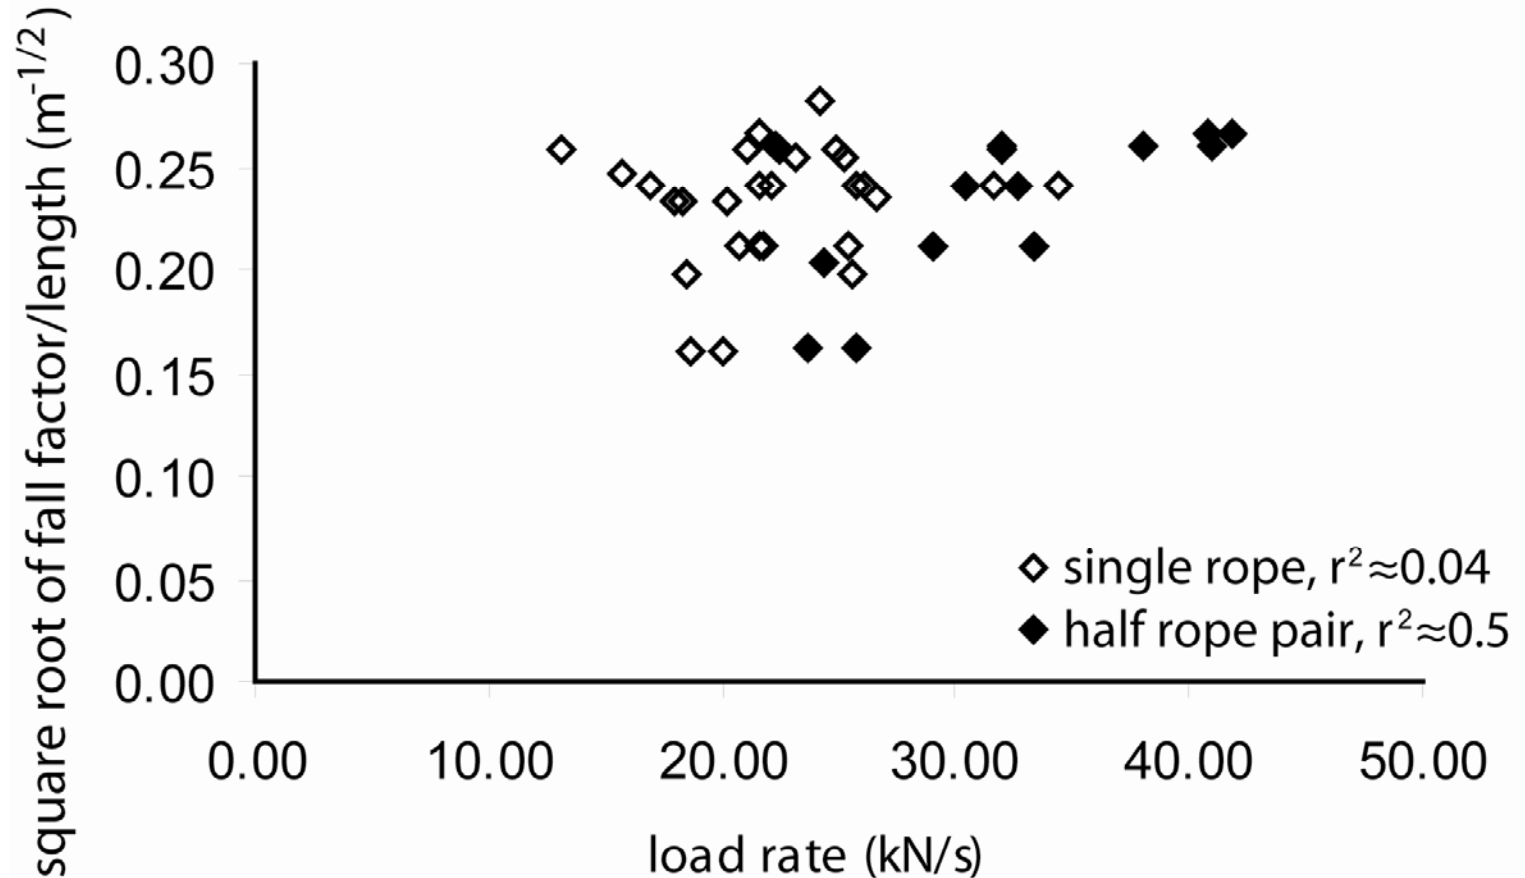

EAS reduce load rate

model compared to data

Mägdefrau data

square root of fall factor/length vs load rate

model and data correlate only loosely

conclusions

as a rule of thumb:

$$Y \propto M \sqrt{\frac{F}{T}}$$

- climbers can apply the rule by protecting the belay and using low “modulus” ropes.
- use EAS and a dynamic belay.
- in the future, the rule might be used to guide the design of better ice screws and perhaps the use of plastic anchor components.
